## ACKNOWLEDGMENTS

---

This investigation was undertaken at the suggestion of Professor H. C. Sherman and carried out under his direction. The author wishes to express to Professor Sherman her appreciation for advice and encouragement received during the course of the work.

The author wishes also to express thanks to Professor A. W. Thomas for helpful suggestions.

# A CRITICAL INVESTIGATION AND AN APPLICATION OF THE RAT GROWTH METHOD FOR THE STUDY OF VITAMIN B.

---

## INTRODUCTION

The term "vitamin B" is here used synonymously with "water soluble B" as a designation for the water soluble growth promoting substance whose existence as an essential constituent of the food was demonstrated by Hopkins<sup>1 & 2</sup>, Osborne and Mendel<sup>3-7</sup>, and McCollum and Davis<sup>8-11</sup> by growth experiments with young mammals, chiefly rats. Whether this is identical with the antineuritic substance studied by Eijkman<sup>12-14</sup>, Funk<sup>15-16</sup>, Williams<sup>17-20</sup> and others through experiments with birds, or with the "bios" of Wildiers<sup>21</sup> which shows a growth promoting property toward yeast, does not concern the present investigation. The recent publication of a monograph *The Vitamins* by the American Chemical Society<sup>22</sup> makes it unnecessary to review previous work at length in this connection.

The importance of vitamin B as a factor in food values makes desirable the standardization of the method of studying this substance so as to permit of quantitative investigation of the relative amounts in different foods or in the same food before and after heating or other treatment to which foods may be subjected in the course of preservation or cooking.

When such methods are sufficiently developed they can also be applied to the quantitative measurement of the concentration of the vitamin at successive steps in attempts to isolate the substance from natural sources and bring it to a condition of maximum purity for the determination of its chemical nature.

For the present investigation white rats were selected as the experimental animal and dried skimmed milk as the vitamin-containing food. Examination of the literature, as well

as the author's experience, shows that the pigeon method for studying the vitamin B content of food, by the power of the substance to prevent or cure polyneuritis, yields rather irregular results<sup>15, 22, 36, 38</sup>. The method of testing for vitamin B by measuring the acceleration of yeast growth is open to the question whether the culture medium is adequate in all other respects and whether it is safe to assume that increased yeast is attributable entirely to the vitamin<sup>23-35</sup>. The nutrition requirements and rate of growth of the rat have been extensively studied by Hopkins<sup>1, 2, 36</sup>, Osborne and Mendel<sup>3-7</sup>, McCollum<sup>8-11</sup> and others. The rat method is therefore the best standardized by previous work. Dr. Harriet Edgeworth<sup>37</sup>, working in this laboratory, after a careful analysis of the yeast and rat growth methods concluded: "The rat growth method involves somewhat larger probable errors than the yeast method, but can be interpreted in terms of B vitamin with much greater certainty and is therefore the preferable method." Skimmed milk in the form of dry powder was chosen as the source of vitamin B, since it furnishes the vitamin in a typical natural state, readily available and uniform. It is easily and accurately manipulated in either large or small quantities and is convenient for study in either the fluid or dry state.

## EXPERIMENTAL PROCEDURE

**Selection and Care of Animals.** The rats used were twenty-eight or twenty-nine days old, this being the time of weaning adopted in this laboratory, and weighed from thirty to sixty-five grams when placed on the experimental diet. The experimental animals all came from mothers on a diet of two-thirds whole wheat, one-third whole milk and sodium chloride, two per cent. of the weight of the wheat (diet 13) or this diet with an addition of ten grams of raw lean beef per adult rat per day (diet 13M). In each experiment, however, care was taken, that equal numbers of comparison and control rats came from mothers on the same diet. The lots were made up in the following manner. If, for example, in one experiment

there were five variations of the diet and ten rats for each variation, then fifty rats were required. Six to eight litters of from five to ten animals each would be needed to supply this number of rats. Each litter was distributed over the five variations as far as it would go. For example, a litter of nine rats would furnish two animals each for four variations and one for the fifth. Then a litter of six rats would provide for one rat where there were two before, and two rats where there was one before, making a total of three rats for each variation of the diet. The remaining thirty-five rats from the various litters were portioned out so that there were ten animals in each lot, and in such a way that the total weight of the rats and the number of males and females on each modification was practically the same.

The experiments were continued for eight weeks, from the beginning of the fifth to the end of the twelfth week of the rat's life, this being the most rapid growth period. A number of experiments were continued for four weeks longer. These last four weeks, however, did not show any significant differences which were not brought out in the growth curves from the fourth through the twelfth week.

When the milk, which was the source of vitamin B, was fed separately from the rest of the diet, the animals were kept in round galvanized iron wire cages, eight inches high and nine inches in diameter, one rat in each cage. In addition to the milk these rats received a vitamin B-free basal ration, of which they ate *ad libitum*. In the experiments in which the rats received the milk mixed with the rest of the diet, which was always before them, six to eight animals were housed in square iron wire cages 11" x 14" x 10". Fresh water was always available. The cages were cleaned as often as seemed necessary, the large cages usually every day and the small round cages three times a week. Each animal was weighed once a week and the food remaining weighed and subtracted from the amount fed, the difference being the amount consumed by the rat or rats during that week.

**Basal Ration and its Preparation.** The basal ration used was planned to contain all the essential food factors in optimum

amounts, with the exception of vitamin B which was lacking. It had the following composition:

Diet 94		per cent.
Casein		18
Butter fat	-	10
Starch		68
Salt mixture (Osborne and Mendel) <sup>40</sup>		4

Later, merely as a factor of safety, cod liver oil was substituted for one-fifth of the butter fat, making diet 107. The ingredients of the diet were weighed out and intimately mixed first by hand and then transferred to a mechanical mixer and stirred for five minutes.

The casein was prepared from the commercial product by purification in the manner suggested by Sherman and Husa (unpublished experiments) as follows: One liter of 60 per cent. alcohol (by weight) was added to 200 grams of casein and the mixture stirred for one-half hour by means of a mechanical stirrer and was then allowed to stand for five and one-half hours. After this period the casein was filtered off through a Buchner funnel and washed once in the funnel with 500 cc. of 60 per cent. alcohol. The casein was again treated with one liter of 60 per cent. alcohol as before but this time was left to stand for eighteen hours. It was filtered off and washed as before with 500 cc. of 60 per cent. alcohol and finally with 500 cc. of 90 per cent. alcohol. The last washing merely facilitates the drying. The casein was removed from the filter and spread out in a thin layer and allowed to become air-dry. Throughout this paper the strength of alcohol used is always given in per cent. by weight.

The butter was melted at a temperature not exceeding 45° C. All the curd, salt and water settles to the bottom of the vessel and may be easily removed when the butter solidifies. The butter fat is again melted at a low temperature, and filtered through filter paper using a hot water funnel.

The salt mixture described by Osborne and Mendel<sup>40</sup> was used. Commercially pure corn starch, which according

to these authors contains no appreciable quantities of the water soluble vitamin furnished the carbohydrate of the diet<sup>30</sup>.

**Source of Vitamin B, Treatment and Manner in Which it Was Fed.** Dried skimmed milk was used as a convenient source of vitamin B. It permits the study of the effect of heat on the vitamin both in the wet and dry state. By using skimmed milk powder from the same lot throughout one experiment, possible variation in vitamin content is eliminated.

The dry milk was heated at 100° C. for six, twenty-four and forty-eight hours in a constant temperature oven. It was spread out in thin layers about one-half inch in thickness and the temperature taken by means of a thermometer extending into the dry milk. Two hours were allowed, which was the time found to be necessary for the milk to come to 100° C. The portions heated six, twenty-four and forty-eight hours respectively actually remained in the oven eight, twenty-six and fifty hours.

The reconstructed milk was prepared by weighing out 100 grams of the air-dry powder and making it up to 1,000 cc. with water. For the heat treatment 250 cc. of this was poured into an Erlenmeyer flask and tightly stoppered with cotton. This was heated in a vigorously boiling water bath for six hours. A thermometer extending into the milk actually recorded a temperature of 99.5° C. to 99.8° C. At the end of six hours the flask was removed from the bath and rapidly cooled under the tap. Since the volume diminished, due to evaporation through the stopper, the milk was again made up to volume before using.

The milk was fed in doses of 8 cc. per rat per day for seven days a week, this, as will later be shown, being the amount which would best reveal any variation in vitamin content. The milk was measured into a small cup by means of a graduated pipette and placed into the cage each day. If the rat did not drink the milk readily, the water cup was removed for the day and replaced in the evening. Usually this treatment brought the desired results. After two to three days all the rats took all the milk that was given them. The milk

heated dry was fed in two ways: (1) mixed with the rest of the diet, replacing 25 per cent. of the starch in diet 94. This ration was always available and the rats ate ad libitum. (2) In another series of experiments the milk, which was heated dry, was reconstructed before feeding by making 25 grams up to a volume of 250 cc. with water. This was fed in doses of 8 cc. per rat per day. The advantage here is that all the rats received exactly the same amount of vitamin per day. Positive controls, animals receiving in the one case the diet containing 25 per cent. of unheated milk and in the other case 8 cc. per day of the reconstructed unheated milk, were run in every case in comparison with the rats receiving the heated food. Negative controls, receiving only the vitamin-free diet were run in almost all but not every experiment. This was done in order to make sure that the basal diet did not vary.

#### THE ADEQUACY OF THE BASAL DIET

In order to prove that the basal ration contained the optimum amounts of the various constituents, it was fed to a series of rats in comparison with diets in which each ingredient of the basal ration, the casein, butter fat and salt mixture, were in turn used in larger amounts. It was thought that perhaps another protein such as extracted meat might prove to be a more adequate protein, or the meat might be more palatable and that therefore the rats would eat more of the basal ration. Consequently diet 94 was also compared with a diet in which extracted meat residue replaced the casein. Commercial extracted meat residue was purified according to the method described for casein (page 7).

TABLE I.

The following diets were used in the comparison:

Diet .....	94	102	103	105	104
	%	%	%	%	%
Casein .....	18	18	23	18	18*
Butter fat .....	10	15	10	10	10
Starch .....	68	63	63	67	68
Salt mixture (O. & M.) <sup>40</sup> ....	4	4	4	5	4

\* Meat residue.

The average growth curves on these various diets were practically identical and the average duration of life varied by only four days. Table II briefly summarizes the results of this series of experiments.

TABLE II.

Summary of average results on diets 94, 102, 103, 104, 105.

Diet	Number of rats	Average initial weight	Average weight at death	Average age at death
94.....	12	47 gms.	34 gms.	61 days
102.....	8	46 "	31 "	65 "
103.....	8	47 "	34 "	64 "
105.....	8	47 "	34 "	63 "
104.....	8	46 "	33 "	62 "

It was thought that the results might be different if vitamin B were added to the diets, in other words if this vitamin was not the limiting factor in the diet. At about this time in the course of the work, it was also thought wise, merely as a factor of safety, to replace 2 per cent. of the butter fat in the diet by cod liver oil. Each rat in this comparison received either diet 107, 108, 109, or 110 with an addition of 7 cc. or 8 cc. of reconstructed skimmed milk. These doses were used, since from experiments reported later in the paper it became apparent that one or the other of these amounts would probably give the best results in the study of the destruction of water-soluble B by heat. 8 cc. was later decided upon as the best dose but the results for both are here given, both being valuable in this connection.

TABLE III.

The following diets were used in the second comparison:

Diet .....	107	108	109	110
	%	%	%	%
Casein .....	18	18	23	18
Butter fat .....	8	13	8	8
Cod liver oil .....	2	2	2	2
Starch .....	68	63	63	67
Salt mixture (O. & M.) <sup>40</sup> .....	4	4	4	5

Table IV gives a summary of the results of the comparison of diet 107 with diet 108 containing 5 per cent. more butter fat, diet 109 containing 5 per cent. more casein and diet 110 with an excess of 1 per cent. salt mixture over that in diet 107.

TABLE IV.

Diet	Reconstructed unheated skimmed milk added	No. of rats	Aver. initial weight	Aver. weight at death or when killed	Aver. age at death or when killed	Gain for 8 weeks
107	0	11	47 gms.	36 gms.	54 days at death	
108	0	10	47 "	36 "	55 " " "	
109	0	10	47 "	36 "	55 " " "	
110	0	9	47 "	34 "	53 " " "	
107	7 cc.	9	48 "	69 "	Killed at 12 weeks	21 gms.
108	7 cc.	10	47 "	84* "	1 dead at 64 days	37 "
					Rest killed at 12 wks.	
109	7 cc.	11	49 "	73 "	Killed at 12 weeks	23 "
110	7 cc.	10	46 "	70 "	" " 12 "	24 "
107	8 cc.	10	47 "	82 "	" " 12 "	35 "
108	8 cc.	12	48 "	81 "	" " 12 "	33 "
109	8 cc.	11	47 "	82 "	" " 12 "	35 "
110	8 cc.	11	47 "	78 "	" " 12 "	31 "

\* 84 gms. is the average weight of 9 rats at 12 weeks of age.

The results of the experiments tabulated in Table IV are the same as those in the previous series (Table II). It appears from the data that the basal rations 94 and 107 furnish optimum amounts of the essential food factors, protein, fat, mineral salts and vitamin A.

#### DETERMINATION OF THE MOST ADVANTAGEOUS DOSE FOR MEASURING HEAT DESTRUCTION OF VITAMIN B IN SKIMMED MILK POWDER.

**Feeding the Milk Separately from the Rest of the Diet.** It was next necessary to determine the amount of milk to feed in order to detect most readily any change in the water soluble B content upon heating the milk. Increasing amounts of milk were superimposed on the basal diet and a study made of the growth curves in relation to size of the dose. The milk was

fed in doses of 2 cc., 4 cc., 6 cc., 8 cc., 10 cc., 12 cc., 15 cc., per rat per day. These amounts were fed without regard to the weight of the rat and the same amount was fed throughout the experimental period. The data are summarized in Tables V and VI and Chart I, Figures I and II.

TABLE V.  
Diet 94 and unheated milk.

No. of rats	Milk cc. per day	Age in weeks										Total gain for 8 wks.	Remarks	
		4	5	6	7	8	9	10	11	12

3	8	45	54	66	77	86	95	99	108	116	71			
6	10	45	56	67	76	85	94	99	101	107	62			
6	12	46	58	74	84	92	99	99	103	113	67			
6	15	48	65	81	90	100	108	107	111	110	62			

K. = killed.

D. = dead.

\* Since all rats did not live till the end of the experimental period, averages could not be given for the last three weeks.

- (1) 4 rats D. at 64, 65, 77, 77 days.  
2 rats K. at end of 12th wk.  
(2) 4 rats D. at 63, 66, 70, 74 days.  
2 rats K. at end of 12th wk.

TABLE VI.  
Diet 107 and unheated milk.

No. of rats	Milk cc. per day	Age in weeks										Total gain for 8 wks.	Remarks
		4	5	6	7	8	9	10	11	12			
		Average weight in grams											
10	0	51	54	52	47	37							see (1) below
10	6	51	61	70	70	66	61	61	62	66	15		
10	8	51	65	78	84	84	83	83	86	91	40		
10	10	50	65	80	90	92	91	95	100	105	55		
10	12	50	67	85	97	102	105	110	115	120	70		

- (1) 37 gms.=average weight at death.  
56 days=average age at death.

It will be noted that in both experiments (Tables V and VI) the largest difference in weight gained for the same difference in milk fed comes between 6 cc. and 8 cc. In order to prove

conclusively that the 8 cc. dose is the best one to use, three lots of six rats each were given diet 94 with the addition of 6 cc., 7 cc., and 8 cc. of skimmed milk respectively per rat per day. The animals receiving 6 cc. of the milk gained an average of 34 grams in eight weeks, those receiving 7 cc. averaged 35 grams gain and the rats fed 8 cc. averaged 56 grams.

Eight cc. of skimmed milk per rat per day is probably the best level at which to feed in order to detect any change in the vitamin B content of the milk, since it is at this level that we get the largest difference in the total gain in weight for eight weeks, as compared with the next lower amount fed. This does not furnish the optimum amount of vitamin B, since further addition of milk gave increased growth in many cases and in the general average.

In another experiment the amount of milk given was varied in accordance with the weight of the rat. Each animal received 0.05, 0.075, 0.10 or 0.125 grams of skimmed milk powder (0.50, 0.75, 1.00 or 1.25 cc. reconstructed milk) per 10 grams of rat per day. The amount of milk fed was calculated on the basis of the weekly weighings, the milk fed each day for a week being determined from the weight of the rat at the beginning of the week. It was expected that this method would yield more consistent results and that the variation among individuals receiving the same amount of vitamin B would be lessened by this method of feeding. The results, however, do not bear out this assumption. A comparison of the weight curves of the individual rats which were fed the same amount of milk throughout the experimental period regardless of body weight, with those of the rats receiving the graduated doses, shows that the former are as uniform as those in the other series. Table VII summarizes the results of the experiments in which the rats received the graduated doses. 0.1 gram of milk per day per 10 grams of rat is apparently the best level at which to feed the milk by this method, since for the same difference in amount of milk given a greater difference in weight gained is observed between this and the next lower amount, than between any other two successive doses. The method was not adopted since it gave no

assurance of having any advantage over the former, and the former was easier of application.

TABLE VII.

Diet 94 and unheated skimmed milk fed in fluid state.

No. of rats	Milk per 10 gms. of rat per day, gms.	Age in weeks										Total gain for 8 wks.	Remarks

(1) 31 gms.=average weight at death.  
55 days=average age at death.

**Feeding the Dried Milk Mixed With the Rest of the Diet.**

For the experiments in which the dried milk was mixed with the rest of the diet, it was essential to determine the proportion in which the milk should be added in order to make the test for possible differences in vitamin B content, most delicate. The starch in diet 94 was replaced by skimmed milk in amounts varying from 2.5 per cent. to 30.0 per cent. The diets are given in Table VIII.

TABLE VIII.

Diet	94	98	97	96	95	99	100	101
	%	%	%	%	%	%	%	%

The greatest difference in rate of growth for a difference of 5 per cent. in the amount of milk contained in the diet, is found between 20 and 25 per cent. Obviously then the ration containing 25 per cent. of skimmed milk powder is the proper one to use in a study of the change in the water soluble B content of skimmed milk powder upon heating.

A study of Tables IX and X further shows a decided difference between the animals from the two sources. Rats from mothers on Diet 13 M grew faster and maintained a higher average weight than the animals from mothers on Diet 13 alone. The young rats from Diet 13 M are evidently more vigorous and therefore make better growth. The data shows that it is essential either to use rats coming from mothers on the same diet or to take the same number of rats from each diet in making up matched lots of rats for comparison.

A typical experiment will suffice to show the variation among the individual animals on the same diet. The average

figures for 8 cc. milk in Table VI were calculated from the data given in Table XII.

### THE EFFECT OF HEAT UPON VITAMIN B IN MILK IN THE DRY AND FLUID STATE.

**Experiments with Reconstructed Skimmed Milk Fed Separately from the Rest of the Diet.** The skimmed milk powder used in this work was heated both dry and in the natural fluid state, in the manner described earlier in this paper. The liquid milk was heated for six hours at 100° C. in a boiling water bath and the dry milk for 6, 24 and 48 hours at 100° C. in a constant temperature oven. In the experiments summarized in Table XIII each rat received 8 cc. of the reconstructed milk per day in addition to the basal ration 107, 8 cc., as has been previously shown, being the dose which would be most likely to reveal any modification in the B content of the milk. When the milk was heated dry it was mixed with water (1 gm. milk in 10 cc. water) before feeding. The advantage of this method of feeding is that each animal receives exactly the same amount of the vitamin-containing food whereas in the experiments in which the milk is mixed with the rest of the food, the amount of vitamin the rat gets depends upon how much food it eats.

TABLE XIII.

Diet 107 and 8 cc. of milk treated in various ways.

No. of rats	Milk treatment	Age in weeks										Total gain for 8 weeks
		4	5	6	7	8	9	10	11	12		
		Average weight in grams										
10	Unheated	53	70	80	82	86	86	88	91	95	42	
10	Heated dry 6 hrs.	54	69	80	83	87	88	89	91	96	42	
10	Heated dry 24 hrs.	54	68	76	77	79	77	78	78	80	26	
10	Heated dry 48 hrs.	53	67	75	78	82	85	85	86	90	37	
10	Heated in fluid state 6 hrs.	54	66	71	67	63	60	57	57	60	6	

The results in Table XIV are those of an experiment similar to the one just described, but in place of 8 cc., each rat received only 7 cc. of milk, this series of experiments having been completed before it was decided that 8 cc. would be the most satisfactory amount. In both experiments all the rats came from mothers on Diet 13 M.

TABLE XIV.

Diet 94 and 7 cc. of milk treated in various ways.

No. of rats	Milk cc.	Milk Treatment	Age in weeks										Total gain for 8 weeks
			4	5	6	7	8	9	10	11	12		
			Average weight in grams										
3	0		42	43	44	38	32 <sup>1</sup>						
3	7	Unheated	45	59	70	71	71	68	64	64	64	19	
4	7	Heated dry 6 hrs.	45	57	72	78	74	71	67	64	62	17	
4	7	Heated dry 24 hrs.	46	59	75	78	74	71	67	63	59	13	
4	7	Heated dry 48 hrs.	40	50	61	66	69	68	64	57	57	17	
4	7	Heated in fluid state 6 hrs.	40	61	68	65	59	53 <sup>2</sup>					

<sup>1</sup> 32 grams = average weight at death, the average age being 53 days.

<sup>2</sup> 53 grams = average weight at death, the average age being 62 days.

There is apparently a measurable destruction of vitamin B when the milk is heated at 100° for 6 hours in the fluid state. The average growth curve for the ten rats receiving 8 cc. of the reconstructed milk heated six hours at 100° C. corresponds very closely to the average curve of the rats receiving 6 cc. of unheated milk (Tables V and VI). This indicates that approximately one-fourth of the total B in the milk was destroyed when the fluid milk was heated for six hours at 100° C.

The seasonal differences in the growth of the rats <sup>1, 2, 42</sup> and the possible seasonal variation in the vitamin content of the milk <sup>1, 2, 41, 42, 43, 44</sup> are eliminated here, since the experiments (Tables V and VI) were carried on at the same time in the early spring, late winter milk from the same lot being used in both series. The four rats receiving 7 cc. of reconstructed milk which had been heated, died at the ages of 50, 60, 66 and 66 days respectively, while the rats getting the same amount of unheated milk lived till the end of the twelfth week when they were killed. This is additional evidence of the destruction of vitamin B by this heat treatment.

Dry heat applied for 6, 24 and 48 hours seems to have little or no deleterious effect, as the weight curves of the control rats receiving unheated milk and of those receiving the heated milk are approximately the same.

**Experiments with Milk Mixed with the Rest of the Diet.** Preliminary experiments reported elsewhere in this paper indicate that a change in the vitamin B content of skimmed milk powder may be most easily observed if the milk is mixed with the rest of the diet in the proportion equal to 25 per cent. of the entire mixture. Therefore the unheated milk of Diet 100 was replaced by the milk heated dry for various periods, 6, 24 and 48 hours. The animals from mothers on Diet 13 M and Diet 13 placed on these diets have been summarized separately in Tables XV and XVI and the combined results are given in Table XVII and Chart II, Figure II. It will be noted here again, as was observed from the results of the experiments in which different amounts of milk replaced the starch in Diet 94 (Tables IX and X) that the rate of growth of the animals from Diet 13 M is greater than that of the animals from Diet 13.

The total food consumed by the animals on Diet 100 and the diets in which the unheated milk of this ration was replaced by the milk heated 6, 24 and 48 hours was practically the same in each case. The rats therefore received essentially the same number of calories and equal amounts of protein, of the mineral elements and of the vitamin containing food on the four different diets.

\* 35 gms.=average weight at death, 64 days being the average age.

The conclusions to be drawn from these regarding the heat destruction of vitamin B in the dry state, confirm those of the previous experiment in which the heated milk was fed separately. The average gain in weight for eight weeks on a control diet containing unheated milk and on the diets containing the milk heated for 6, 24 and 48 hours is the same. There is evidently no destruction of the vitamin by this treatment or the amount of destruction is too small to be detected by either of the methods employed in the present work.

## SUMMARY

A quantitative method for the determination of relative amounts of vitamin B is described. The work comprises eleven comparative studies with a total of thirty-eight variations of the basal diet and includes over six hundred quantitative studies of the growth of young rats.

An adequate basal ration is described which contains optimum amounts of all the food factors necessary for the growth of young rats with the exception of vitamin B.

The most advantageous quantities of milk to feed in order to detect possible differences in the vitamin B content were 8 cc. of skimmed milk or 0.8 gram of skimmed milk powder per rat per day when the milk was fed separately from the rest of the diet; or 25 per cent. of the total food mixture when the skimmed milk powder was mixed with the basal ration.

Feeding the basal ration under the conditions described to experimental animals of suitable age and size and sufficiently known dietary history, it is believed to be possible to detect a variation certainly of 25 per cent. and probably of 15 per cent. in the vitamin B content of the food tested.

There was no evidence of destruction of vitamin B in milk powder heated dry at 100° C. even when this heating was continued for forty-eight hours. When the milk was heated in the fluid state for six hours at 100° C. there was appreciable destruction of vitamin B. Apparently about one-fourth of the vitamin was destroyed. Vitamin B is therefore very stable to heating at 100° C. in the dry state, but somewhat less stable when heated at the same temperature in water solution.
